AUDITED BY

 **DRIVEN.**
security

Disclaimer

Accepting a project audit is a sign of confidence and is usually the first indicator of trust for a project, but it does not guarantee that a team will not remove all liquidity, sell tokens, or engage in any other type of fraud. There is also no way to prevent private sale token holders from selling their tokens. It is ultimately your responsibility to read all documentation, social media posts, and contract code for each particular project in order to draw your own conclusion and define your own risk tolerance.

DRIVENsecurity accepts no responsibility for any losses or speculative investments. This audit's material is given solely for informational reasons and should not be construed as investment advice.

Project Details

Project name: Elitheum

Contract Address:

0x5774f0e73bb1c0957dd7442b2442c6f77c10aaa1

Contract Creator:

0x2238f43070282588dc9bb5cbeb4ae99a7ac97914

Blockchain: Binance Smart Chain / Solidity

Contract Name: Elitheum

Token Ticker: ELTHM

Decimals: 9

Transactions Count: 884

Project Website: <https://elitheum.co/>

First check: 22.08.2021

Overview

General issues

- Security issues **[passed]**
- Gas & Fees issues: 1 low-severity issue
- ERC errors: **[passed]**
- Compilation errors: **[passed]**
- Design logic: **[passed]**
- Timestamp dependence: **[passed]**

Security against cyber-attacks

- Private user's data: **[secured]**
- Reentrancy: **[passed]**
- Cross-function Reentrancy: **[passed]**
- Front Running: **[passed]**
- Taxonomy attacks: **[passed]**
- Integer Overflow and Underflow: **[passed]**
- DoS (Denial of Service) with Unexpected revert: **[passed]**
- DoS (Denial of Service) with Block Gas Limit: **[passed]**
- Insufficient gas griefing: **[passed]**
- Forcibly Sending BNB to a Contract: **[passed]**

In-depth analysis

Gas and Fees issues: 1 low-severity issue

We observed that the following functions:

- `includeInReward()`
- `_getCurrentSupply()`

are using FOR loops with dynamic array so the number of iterations is uncontrolled.

To avoid exceeding the block gas limit, use stable variables in the FOR loops or implement mapping.

ERC issues: 0

`decimals()` functions returns a `uint8` parameter. This function is safe and secured – it's only purpose is to show the decimals.

In-depth analysis

Security issues: 0

We observed that the following functions:

- `getTime()`
- `lock()`
- `unlock()`
- `swapTokensForEth()`
- `swapETHForTokens()`
- `addLiquidity()`

are utilizing `block.timestamp` variable. That means the miner has the ability to "choose" the block.

To a certain level, a timestamp can be used to alter the outcome of a transaction in a mined block.

However, since those functions are private (can be called only by the contract owner) do not generate sensitive information, the functions listed above are safe and secure.

In-depth analysis

Compilation issues: 0

Functions that can be called by owner

Exclude / include address from fees or/and rewards:

- `excludeFromFee`
- `excludeFromReward`
- `includeInFee`
- `includeInReward`

Ownership:

- `lock` – Renounce to ownership for a period of time ;
- `renounceOwnership`;
- `unlock` – Will be automatically called when the unlock time will arrive ;
- `transerOwnership` – transfer the ownership to another address;

In-depth analysis

Functions that can be called by owner

Fees and operations for transactions:

- **setLiquidityFeePercent** - liquidity fee in %;
- **setMarketingAddress** - set the marketing wallet;
- **setMarketingDivisor**
- **setMaxTxAmount** - maximum amount per transaction
- **_minimumTokensBeforeSwap** - minimum amount to buy/sell;
- **setTaxFeePercent** - rewards;

Other functions:

- **prepareForPreSale()** - cancel the fees and set **_maxTxAmount = 2 Trillions**;
- **afterPreSale()** - set the **_taxFee** to 1, **_liquidityFee** to 21 and **_maxTxAmount = 100 Billions**;
- **buyBackLimit**;
- **setBuyBackEnabled** - enable or disable Buy Back function;

Penetration testing

Re-entrancy

What is "Re-entrancy"?

A re-entrancy attack can arise when you write a function that calls another untrusted contract before resolving any consequences. If the attacker has authority over the untrusted contract, he can initiate a recursive call back to the original function, repeating interactions that would otherwise not have occurred after the effects were resolved.

Attackers can take over the smart contract's control flow and make modifications to the data that the calling function was not anticipating.

To avoid this, make sure that you do not call an external function until the contract has completed all of the internal work.

Test: [passed]

Penetration testing

Cross-function Re-entrancy

What is "Cross-function Reentrancy"?

When a vulnerable function shares the state with another function that has a beneficial effect on the attacker, this cross-function re-entrancy attack is achievable. This re-entrancy issue that is the employment of intermediate functions to trigger the fallback function and a re-entrancy attack is not unusual.

Attackers can gain control of a smart contract by calling public functions that use the same state/variables as "private" or "onlyOwner" functions.

To avoid this, make sure there are no public functions that use private variables, and avoid calling routines that call external functions or use mutex (mutual exclusion).

Test: [passed]

Penetration testing

Front Running

What is "Front Running"?

Front-running indicates that someone can obtain prior information of transactions from other beneficial owners by technology or market advantage, allowing them to influence the price ahead of time and result in economic benefit, which usually results in loss or expense to others.

Since all transactions are visible in the block explorer for a short period of time before they are executed, network observers can see and react to an action before it is included in a block.

Attackers can front-run transactions because every transaction is visible to the blockchain, even if it is in the "processing" or "indexing" state. This is a very low security vulnerability because it is based on the blockchain rather than the contract.

The only possible attack is seeing transactions made by bots. Using transaction fees, you can avoid bots.

Test: [passed]

Penetration testing

Taxonomy attacks

Those taxation attacks can be made in 3 ways:

- 1) Displacement – performed by increasing the gasPrice higher than network average, often by a multiplier of 10.
- 2) Insertion – outbidding transaction in the gas price auction.
- 3) Suppression (Block Stuffing) – The attacker sent multiple transactions with a high gasPrice and gasLimit to custom smart contracts that assert to consume all the gas and fill up the block's gasLimit.

This type of attacks occurs mainly for exchanges, so this smart contract is secured.

Test: [passed]

Penetration testing

Integer Overflow and Underflow

– overflow: An overflow occurs when a number gets incremented above its maximum value.

In the audited contract: `uint8 private _decimals = 9;`

Test: **[passed]**

(`_decimals` can't reach a value bigger than it's limit)

– underflow: An overflow occurs when a number gets decremented below its maximum value.

Test: **[passed]**

(there are no decrementation functions for parameters and users can't call functions that are using uint values);

This contract use the update version of SafeMath for Solidity 0.8 and above.

Test: **[passed]**

Penetration testing

DoS (Denial of Service) with Unexpected revert

DoS (Denial of Service) attacks can occur in functions when you attempt to transmit funds to a user and the functionality is dependent on the successful transfer of funds.

This can be troublesome if the funds are given to a bad actor's smart contract (when they call functions like "Redeem" or "Claim"), since they can simply write a fallback function that reverts all payments.

Test: [passed]

There are no functions that deliver money to users, attackers are unable to communicate using a contract with fallBack functions

Penetration testing

DoS (Denial of Service) with Block Gas Limit

Each block has an upper bound on the amount of gas that can be spent, and thus the amount computation that can be done. This is the Block Gas Limit. If the gas spent exceeds this limit, the transaction will fail. This leads to a couple possible Denial of Service vectors.

Test: [passed]

Penetration testing

Insufficient gas grieving

This attack can be carried out against contracts that accept data and use it in a sub-call on another contract.

This approach is frequently employed in multisignature wallets and transaction relayers. If the sub-call fails, either the entire transaction is rolled back or execution is resumed.

Test: [passed]

Users can't execute sub-calls.

Penetration testing

Forcibly Sending BNB to a Contract

Test: [passed]

Thank you!

In-depth analysis

Security issues: 0

We observed that the following functions:

- `_functionCallWithValue`
- `constructor ()`
- `swapTokensForEth`
- `swapETHForTokens`

are vulnerable to re-entrancy attacks.

Since those functions are private (can be called only by the contract owner), the functions listed above are safe and secure.
